

Do Competent Women Receive Unfavorable Treatment?

Abstract

Do competent women receive unfavorable treatment than equally competent men? While literature finds that competent women are perceived as less likable, its direct effect on women's career is not well investigated. I study this question in a laboratory experiment where unfavorable treatment has material consequences. I find that neither men nor women treat competent women less favorably; if anything, both men and women treat competent women slightly more favorably than equally competent men. The findings provide a piece of evidence that competent women may not necessarily receive unfavorable treatment, which may shed new light on hiring and promotion practices in labor markets.

Keywords: competence, gender bias, labor markets, laboratory experiment

*Department of Economics, University of Bologna. Email: yuki.takahashi2@unibo.it. I am grateful to Maria Bigoni, Natalia Montinari, and Siri Isaksson whose feedback was essential for this project. I am also grateful to participants of the experiment for their participation and cooperation. Laura Anderlucci, Tiziano Arduini, Francesca Barigozzi, Enrico Cantoni, Chiara Natalie Focacci, Margherita Fort, Catalina Franco, Fabio Landini, Annalisa Loviglio, Valeria Maggian, Joshua Miller, Eugenio Proto, Tommaso Sonno, Alessandro Tavoni, Bertil Tungodden, ESA Experimental Methods Discussion group, and the University of Bologna's PhD students all provided many helpful comments. This paper also benefited from participants' comments at the Applied Young Economist Webinar, the BEEN Meeting, seminars at Ca' Foscari University, the NHH, and the University of Bologna. Veronica Rattini and oTree help & discussion group kindly answered my questions about oTree programming. Lorenzo Golinelli provided excellent technical and administrative assistance. The pre-analysis plan is available at the OSF registry: <https://osf.io/ypsmx>.

1 Introduction

Literature argues that people consider competent women as less likable than equally competent men (Heilman 2001; Rudman and Phelan 2008). This is also a view shared by several top female corporate executives.¹ Being considered as less likable can negatively affect many aspects of workplace experiences which in turn lower productivity, but it is unclear whether it has direct material consequences; that is, whether competent women receive unfavorable treatment in decisions such as hiring and promotion. Indeed, this question has been explored mostly by means of questionnaires and hypothetical decisions (Heilman et al. 2004; Phelan, Moss-Racusin, and Rudman 2008; Rudman and Fairchild 2004; Rudman 1998; Rudman et al. 2012).

Evidence from decisions with material consequences mainly comes from audit studies and is mixed: while Quadlin (2018) finds unfavorable treatment, Ceci and Williams (2015) and Williams and Ceci (2015) do not. One possible reason for this mixed evidence is employers' wrong prior belief about competent women's personality which tends to be negative as evidenced by the literature: because employers have to work with their employees for a long period of time, they want to hire people whom they are comfortable to work with. However, their prior must be updated once the employers see the actual job applicants in the interview. Also, in promotion decisions, employers or managers must know a potential candidate well and their prior belief must play only a weak role.

In this paper, I tackle this question by means of a controlled laboratory experiment. I use dictator game allocation as a measure of favorable and unfavorable treatment with clear material consequences and exogenously vary the recipient's gender and competence. Dictator game allocation is frequently used to measure social distance between two people (e.g., Charness and Gneezy 2008; Leider et al. 2010) and used to study employer-employee relationship (Rosenblat 2008).² I measure competence by an IQ test, an attribute people are about (Eil and Rao 2011; Zimmermann 2020).³

In the experiment, participants first work on an incentivized IQ test. After the test, participants are randomly assigned to a group of six and receive a ranking of their IQ within their group. Once they answer the comprehension questions about their IQ rank, three of the six members are randomly chosen to be dictators and play three rounds of dictator game with the other three members chosen to be recipients, observing the recipients' facial photos and first names – both of which convey information about gender – and the IQ ranks.⁴

Using dictator IQ fixed effects and exploiting random grouping of participants to address

1. For example, in her book *Lean In: Women, Work, and the Will to Lead*, the Facebook's Chief Operating Officer Sheryl Sandberg expresses her view as follows: "If a woman is competent, she does not seem nice enough. If a woman seems really nice, she is considered more nice than competent. Since people want to hire and promote those who are both competent *and* nice, this creates a huge stumbling block for women" (Sandberg 2013).

2. Rosenblat (2008) uses dictator game to examine the role of beauty in employer-employee relationship because "dictator games exemplify a negotiation in which one party has very limited bargaining power and must rely on the generosity of his or her counterpart" (p. 468).

3. The experimental design, the hypotheses, and the empirical strategy are pre-registered at the OSF registry: <https://osf.io/ypsmx>. However, there are a number of changes to the pre-analysis plan discussed in appendix A.

4. The use of photos follows recent literature and allows the dictators to infer the gender of the recipients in a natural way as they would do in their daily life (Babcock et al. 2017; Coffman 2014; Isaksson 2018), but I address the possibility that recipients' gender-specific characteristics (e.g. women may smile more often in a photo) affect dictators' allocation.

the endogeneity of participants' IQ and recipients' gender, I do not find a significant difference between dictators' allocation to competent women and to competent men; if anything, dictators allocate slightly more to competent women. The point estimate of the difference is positive and statistically indistinguishable from 0. The lower bound of the difference is -3.7% of the dictator endowment, which is quantitatively much smaller (2.4-3.1 times smaller) in absolute value than the effect sizes of the other dictator game experiments studying the role of social distance. These results hold across the whole distribution of dictators' allocation and even when I separately examine male and female dictators' allocation. All results control for recipients' gender-specific preference for allocation (e.g. women smile more often than men) using the difference in allocation to incompetent women and men as a control group.⁵ These findings suggest that competent women do not receive unfavorable treatment in decisions involving material consequences such as hiring and promotion.

This paper mainly relates to two strands of literature. The first focuses on the tradeoff women face between being competent and being likable. The literature finds that people perceive female leaders (Heilman, Block, and Martell 1995; Heilman and Okimoto 2007; Rudman and Kilianski 2000) and competent women (Heilman et al. 2004; Rudman 1998) negatively. It also finds that people evaluate competent women negatively, but these results are obtained in set-ups without real consequences (Phelan, Moss-Racusin, and Rudman 2008; Rudman and Fairchild 2004; Rudman et al. 2012). However, the studies about evaluations towards competent women with real consequences find mixed evidence: while Quadlin (2018) finds top-performing female college students less favorable treatment in hiring than equally qualified male students, Ceci and Williams (2015) and Williams and Ceci (2015) find qualified female applicants for assistant professor positions receive equal or more favorable treatment than equally qualified male applicants. My results suggest that the employers' prior belief about competent women may be driving these mixed findings.

When the consequence of their evaluation is not immediately clear, people seem to evaluate women in traditionally male occupations more critically: Boring (2017) and Mengel, Sauermann, and Zölitz (2019) find that female university instructors receive lower student evaluation. There is also evidence that female economists' work are undervalued (Koffi 2019; Sarsons et al. 2020) and female university faculty are less likely to get promotion (De Paola, Ponzio, and Scoppa 2018). However, these critical evaluations may simply reflect the lack of women in these occupations and thus people do not have enough prior information about women's competence, rather than taste-based discrimination. Sarsons (2019) finds that female surgeons receive a more negative evaluation for their failure and Ditonto (2017) finds that voters care more about female politicians' competence than male politicians' competence. Also, Bohren, Imas, and Rosenberg (2019) find that while women initially receive lower credits than men in their contributions to an online mathematics discussion forum, they receive higher credits than men after they accumulate enough positive evaluations. In addition, Coffman, Exley, and Niederle (2020) find that experimental employers are less likely to "hire" female workers over male workers, but they

5. While dictators only see the recipients' IQ relative to theirs and thus the competence measure is relative to theirs, dictators do not see their IQ at the time they play dictator games. Indeed, in the real world, we do not have an absolute measure of other people's competence but evaluate relative to some benchmark. Nevertheless, I provide evidence that relative and absolute competence distinction does not matter for my results.

are equally less likely to hire participants born in even-month who has the same performance distribution as female workers. My findings are compatible with the explanation that people do not have enough prior information about women’s competence, and they give fair evaluations to women once they show they are competent.

2 Experiment

2.1 Design and procedure

The experiment consists of two parts as shown in figure 1; instructions for each part are only delivered at the end of the previous part. Participants earn a participation fee of 2.5€ for their participation.

FIGURE 1: OVERVIEW OF THE EXPERIMENT

Notes: This figure shows an overview of the experiment discussed in detail in section 2.1.

Pre-experiment: Random desk assignment & photo taking

After registration at the laboratory entrance, participants are randomly assigned to a desk. Before the start of part 1, participants take their facial photos at a photo booth and enter their first name on their computer. After that, we experimenters go to each participant’s desk to check that their photo and first name match them to ensure all participants that other participants’ photos and first names are real, following Isaksson (2018).

Part 1: IQ test

In part 1, participants work on an incentivized 9 IQ test questions for 9 minutes. I use Bilker et al. (2012)’s form A 9-item Raven test which predicts one’s IQ measured with the full-length Raven test with more than 90% accuracy. Participants receive 0.5€ for each correct answer. They receive information about how many IQ test questions they have solved correctly only at the end of the experiment. I use IQ as the measure of competence because previous studies find it is an attribute people care most about (Eil and Rao 2011; Zimmermann 2020).

After the IQ test, participants make an incentivized guess on the number of IQ test questions they have solved correctly: they receive 0.5€ if their guess is correct. The answer to this question measures their over-confidence level. They receive feedback on this guess only at the end of the experiment.

Following Eil and Rao (2011), six participants are randomly grouped, and they are informed of the ranking of their IQ relative to other group members. Ties are broken randomly. They then have to answer a set of comprehension questions as shown in figure 2 in order to proceed to the next part.

FIGURE 2: IQ RANK ASSIGNMENT AND THE COMPREHENSION QUESTIONS

Feedback

Among your 6 group members including you, you received **Rank 4**.

Among your 6 group members, how many people performed better than you in the IQ test?

Among your 6 group members, how many people performed worse than you in the IQ test?

Next

Notes: This figure shows an example of the IQ rank assignment and the comprehension questions. In this example, the participant was ranked 4th from the top within a group of 6 participants. Thus, the answer to the first question is 3 (three participants performed better in the IQ test) and the second question is 2 (two participants performed worse in the IQ test).

Part 2: Dictator game

In part 2, three participants in each group are randomly chosen to become dictators and the other three participants become recipients. Dictators are paired with the three recipients in their group one by one in a random order, receive an endowment, and play a dictator game. When they play the dictator game, dictators observe the recipients' facial photo and first name and IQ rank. The use of photo allows me to convey information about gender of other participants in a natural way as in the recent literature (Babcock et al. 2017; Coffman 2014; Isaksson 2018).⁶ Dictators are also told that their allocation decisions are anonymous except for the experimenters: they are told that their allocation is paid to the recipients as a "top-up" to their earnings. Dictators decide allocation by moving a cursor on a slider where the cursor is initially hidden to prevent anchoring, as shown in figure 3. I use a cursor to make it more cognitively demanding to figure out fair allocation, which is shown to increase more self-interested decisions (Exley and Kessler 2019). I also vary the endowment across rounds to make each dictator game less repetitive: 7€ for 1st and 3rd rounds, 5€ for 2nd round. At the end of the experiment, one out of three allocations is randomly chosen for each participant as earnings for this part.⁷

I also collect an indirect measure of dictators' beliefs on how many IQ test questions the paired recipients have solved correctly. To prevent the belief elicitation to affect or be affected by the dictator game, I exploit the random assignment of participants to dictators and recipients (derived from the random desk assignment) and use recipients' beliefs as a proxy for dictators' beliefs. Specifically, while dictators are playing the dictator game, recipients are paired with the other two recipients in the same group one by one in random order and make incentivized guesses on how many IQ test questions they have solved correctly, observing the other two

6. To address the non-anonymity of showing facial photo and first name, I ask participants how well they know the paired participants on a scale of 4 (did not know at all, saw before, knew but not very well, knew very well). I ask this question twice to make sure they do not answer randomly: right after the three dictator games or two guesses and in the post-experimental questionnaire.

7. For each dictator for each round, one of the three recipients in the same group is randomly chosen *without replacement* and the dictator allocates the endowment between themselves and the recipient. Thus, it is possible that two dictators play dictator game with the same recipient in the same round. At the end of the dictator games, each participant has three allocations, and one of which is randomly chosen for payment.

FIGURE 3: DICTATOR’S ALLOCATION SCREEN

Round 1 of 3

Neve

Rank 5

You have received **7€** for this round.

You have been paired with **Neve**.

Please allocate the endowment between yourself and Neve. When you click the line below, a cursor appears. You can move the cursor by dragging it. Please move the cursor to your preferred position to determine the allocation.

You **Neve**

Next

Notes: This figure shows an example of a dictator’s allocation screen. In this example, the dictator is playing the first round and paired with a recipient whose first name is Neve with IQ rank 5.

recipients’ facial photo, first name, and IQ rank. Each correct guess gives them 0.5€.

Post-experiment: Questionnaire

After the dictator game and guessing are over, participants are told their earnings from the IQ test, dictator game, and the guesses. Before receiving their earnings, participants answer a short questionnaire about their demographics that are used for balance tests and robustness checks.

2.2 Implementation

The experiment was computerized and programmed with oTree (Chen, Schonger, and Wickens 2016), and conducted in English during November-December 2019 at the Bologna Laboratory for Experiments in Social Science (BLESS). I recruited 390 students of the University of Bologna via ORSEE (Greiner 2015) who (i) were born in Italy, (ii) available to participate in English experiments, and (iii) had not participated in gender-related experiments in the past (as far as I could check). The number of participants was based on the power simulation in the pre-analysis plan to achieve 80% power.⁸

8. I exclude the 1st session data because of the problem discussed in appendix A. Nevertheless, the results including the 1st session data give me the same conclusions and are available upon request.

The average length of a session was 70 minutes including registration and payment. The average payment per participant was about 10€ including the participation fee and 1.5€ of gratuity for photo use in another experiment (which I asked for recipients only). I ran 24 sessions in total and the number of participants in each session varied from 12 to 30 and was a multiple of 6.

I limit participants to Italy-born students so that their first name and photo do not signal ethnicity, race, or cultural background. As a further attempt to reduce variance, I exclude recipients with non-Italian sounding name,⁹ and whom the dictator declared they knew them “very well” at least once.

These data screenings leave me 390 participants, 195 dictators, and 558 observations (with dictators’ allocation as the unit of observations).

3 Empirical strategy

I estimate the following equation with OLS:

$$Allocate_{ij} = \beta_0 + \beta_1 IQHigher_{ij} + \beta_2 Female_j + \beta_3 IQHigher_{ij} * Female_j + IQFE_i + X'_{ij}\gamma + \epsilon_{ij} \quad (1)$$

where each variable is defined as follows:

- $Allocate_{ij} \in [0, 1]$: dictator i ’s allocation to recipient j as a fraction of endowment.
- $IQHigher_{ij} \in \{0, 1\}$: an indicator variable equals 1 if recipient j ’s IQ is higher than dictator i .
- $Female_j \in \{0, 1\}$: an indicator variable equals 1 if recipient j is female.
- $IQFE_i := \sum_{l=2}^9 \theta^l e_i^l$: fixed effects for the dictators’ IQ (number of IQ test questions they have solved correctly), where $e_i^l \in \{0, 1\}$ is an indicator variable equals 1 if dictator i ’s IQ is $l=1, \dots, 9$, 0 otherwise.
- X_{ij} : a set of additional covariates to increase statistical power and to address potential imbalance.¹⁰
- ϵ_{ij} : omitted factors that are correlated with dictator i ’s allocation to recipient j conditional on covariates.

Dictator’s IQ fixed effects is included following Zimmermann (2020) so that the coefficients in equation 1 capture allocation differences due to the recipients’ IQ, not the dictators’.¹¹ I cluster standard error at dictator level (Liang and Zeger 1986) and apply Pustejovsky and Tipton (2018)’s small cluster bias adjustment to address potential inflation of the type I error rate due

9. Although it is easy to distinguish Italian and non-Italian sounding names, to make sure not to misclassify, I asked the laboratory manager who was native Italian to check participants’ first names after each session.

10. The covariates include dictator characteristics (age, gender dummy, region of origin dummy, social science major dummy, STEM major dummy, post-bachelor dummy, over-confidence level), recipient characteristics (age, region of origin dummy), round fixed effects, and fixed effects for proximity between the dictator and the recipient. The full description of the covariates is in appendix B.

11. This is because people with different IQ (cognitive ability) may have a different distributional preference. For example, Almås et al. (2017) find that people from a low socio-economics family – which can be correlated with their cognitive ability – hold stronger egalitarian views than people from a middle or a high socio-economic family. Fisman et al. (2015) find that students in a top US law school – who presumably are smarter than average US citizens – are more meritocratic and more efficiency-oriented than average US citizens.

to moderate cluster size.¹²

Table 1 shows what the coefficients in equation 1 identify. β_1 identifies the allocation difference to male recipients with higher and lower IQ which captures dictators’ distributional preference, among other effects. β_2 identifies the allocation difference to female and male recipients with lower IQ, namely every difference due to the recipients being female (e.g. women smile more and dictators like to give more to smiling people due to closer social distance). β_3 identifies the interaction of these two effects. Therefore, the allocation difference between female and male recipients with higher IQ is identified by $\beta_2 + \beta_3$, while the main effect of interest, the same allocation difference after controlling for the recipients’ any gender-specific effects, is identified by β_3 . Note that only the relative IQ matters because dictators only observe the recipients’ IQ relative to themselves (and I control for dictators’ IQ). Later, I will elaborate on this point more.¹³

TABLE 1: DICTATOR’S ALLOCATION IDENTIFIED BY EQUATION 1

| | | Recipient’s gender | |
|----------------|--------|-----------------------------------------|---------------------|
| | | Female | Male |
| Recipient’s IQ | Higher | $\beta_0 + \beta_1 + \beta_2 + \beta_3$ | $\beta_0 + \beta_1$ |
| | Lower | $\beta_0 + \beta_2$ | β_0 |

Notes: This table shows what the coefficients in equation 1 identify. Each cell represents dictator’s allocation to recipients with higher (first row) or lower (second row) IQ and whose gender is female (first column) or male (second column).

4 Results

4.1 Data description

Summary statistics Table 2 summarizes the data after excluding participants and observations discussed in subsection 2.2. Looking at panels A and B, participants’ average IQ level (number of IQ test questions solved correctly) is about 7 (with a maximum 9) and gender is roughly balanced. Also, dictators took nearly 2 minutes to solve the feedback questions on their IQ rank. Looking at panel C, most dictators did not know the paired recipients (after excluding pairs in which dictator knew the recipient “very well”). Looking at panel D, an average dictator allocated to paired recipients 40% of their endowment and the residualized standard deviation shows that variation in allocation within each IQ is as large as overall variation in allocation.¹⁴

12. For cross-sectional data, I instead use HC2 heteroskedasticity-robust standard error (MacKinnon and White 1985) with Bell and McCaffrey (2002)’s small sample bias adjustment.

13. While there can be beauty premium that people are more generous to physically attractive people (Landry et al. 2006) which also affects dictators’ allocation (Rosenblat 2008), as long as participants in my sample care others’ physical attractiveness no more or no less than general population, it is not a confounding factor. Even if higher IQ people, women, or/and higher IQ women are more physically attractive than lower IQ people, men, or/and lower IQ women, it is the premium they also receive in the workplace.

14. Residualized standard deviation is standard deviation of residual of regression of the dictator game allocation as a fraction of endowment on IQ fixed effects.

The latter indicates that there is enough variation in allocation I can exploit in my empirical specification (which uses dictator’s IQ fixed effects).

TABLE 2: SUMMARY STATISTICS: DICTATOR DATA

| | Mean | SD |
|---------------------------------------------------------------|--------|-------|
| <i>Panel A: Dictators</i> | | |
| IQ level | 6.69 | 1.23 |

| Age | 23.47 | 2.72 |
| Female | 0.53 | 0.50 |
| From Emilia-Romagna | 0.18 | 0.39 |
| Humanities | 0.46 | 0.50 |
| Social sciences | 0.19 | 0.40 |
| STEM | 0.35 | 0.48 |
| Post bachelor | 0.46 | 0.50 |
| Overconfidence | 0.43 | 0.76 |
| Time on feedback (sec.) | 107.60 | 95.60 |
| Observations | | 195 |
| <i>Panel B: Paired recipients</i> | | |
| IQ level | 6.84 | 1.16 |
| IQ rank | 3.42 | 1.74 |
| IQ higher | 0.53 | 0.50 |
| Age | 23.35 | 2.77 |
| Female | 0.47 | 0.50 |
| From Emilia-Romagna | 0.20 | 0.40 |
| Observations | | 558 |
| <i>Panel C: Proximity</i> | | |
| Did not know at all | 0.96 | 0.19 |
| Knew but not well | 0.03 | 0.17 |
| Saw before | 0.01 | 0.09 |
| Observations | | 558 |
| <i>Panel D: Dictator’s allocation (fraction of endowment)</i> | | |
| Allocation | 0.40 | 0.24 |
| Allocation (residualized) | | 0.24 |
| Observations | | 558 |

Notes: This table shows summary statistics for the full sample: the dictators’ and the paired recipients’ characteristics, how well dictators knew the paired recipients, and dictators’ allocation. Recipients whose name is non-Italian sounding and whom the dictator declared they knew them “very well” at least one are not included. Standard deviation of residualized allocation is standard deviation of residual of regression of the dictator game allocation as a fraction of endowment on IQ fixed effects.

Figure C1 shows empirical density (panel A) and empirical distribution (panel B) of dictators’ allocation to further elaborate panel D of table 2. First, panel A shows that nearly 45% of dictators have chosen equal allocation. Second, the empirical distribution of allocation in panel B resembles the empirical distribution of allocation in Bohnet and Frey (1999)’s one-way identification treatment which also shows recipients’ face to the dictators.

Balance test For coefficients in equation 1 to have causal interpretation, (i) the dictator’s IQ rank must be exogenous conditional on the dictator’s IQ fixed effects and (ii) dictators face recipients of different gender and IQ in a balanced way again conditional on the dictator’s IQ fixed effects. While these are ex-ante ensured by the random desk assignment, they might be unbalanced ex-post.

Table 3 presents regressions of various dictator characteristics on their IQ rank with dictator IQ fixed effects and show that none of the IQ ranks is correlated with their characteristics, providing evidence to support the former point.

TABLE 3: BALANCE TEST: IQ RANK

| Outcome: | Age | Female | From Emilia-Romagna | Humanities | Social sciences | STEM | Post bachelor | Over-confidence |

| IQ rank = 5 | 0.534 (0.959) | 0.092 (0.165) | 0.062 (0.128) | -0.220 (0.175) | 0.166 (0.128) | 0.054 (0.165) | 0.061 (0.156) | 0.158 (0.271) |
| IQ rank = 6 | -0.040 (1.093) | 0.070 (0.191) | 0.021 (0.147) | -0.368* (0.201) | 0.442*** (0.162) | -0.074 (0.173) | 0.013 (0.191) | 0.346 (0.306) |
| Dictator IQ FE | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ |
| F statistic | 0.571 | 0.634 | 0.704 | 0.697 | 1.91* | 0.626 | 0.739 | 0.83 |
| R-squared | 0.040 | 0.067 | 0.040 | 0.042 | 0.074 | 0.062 | 0.027 | 0.032 |
| Observations | 195 | 195 | 195 | 195 | 195 | 195 | 195 | 195 |

Notes: This table shows balance across dictators with different IQ ranks. The estimates are obtained by running OLS regression of various dictator characteristics on IQ rank dummies with dictator IQ fixed effects. The F statistic shows the joint significance of IQ rank = 2 to IQ rank = 6 dummies. HC2 heteroskedasticity-robust standard errors with Bell and McCaffrey (2002)’s small sample bias adjustment are reported below each coefficient estimate. Unit of observation: dictator. Significance levels: * 10%, ** 5%, and *** 1%.

Tables 4 and 5 present results of equation 1, but replace the outcome variable with various dictator, recipient, round, and dictator-recipient proximity indicators, and show that no particular characteristics are correlated with recipients of different gender and IQ. While a few characteristics are correlated with specific recipients – dictators’ and recipient’s region of origin (From Emilia-Romagna), dictator’s social science major, and recipient’s age – they can happen by chance and I control them in the main regression.

4.2 Main results

Table 6 presents the results with all dictators. Column 1 presents estimate without controlling for dictator’s IQ and shows the direction of the bias without including dictator IQ fixed effects: although statistically insignificant, dictators with lower IQ allocate more to recipients with higher IQ regardless of the recipients’ gender as shown by the coefficient estimate on $IQHigher_{ij}$, biasing the estimate upwards. From columns 2 to 5, I gradually increase the number of covariates to check the robustness of my main specification in column 5. They show that the coefficient

Notes: This table shows that dictators were matched recipients of different gender and IQ in a balanced way even ex-post. The estimates are obtained by running OLS regression of various recipient characteristics and round and proximity dummies on covariates of interest with dictator IQ fixed effects. The F statistic shows the joint significance of all covariates. The standard errors are clustered at the dictator level with Pustejovsky and Tipton (2018)’s small cluster bias adjustment are reported below each coefficient estimate. Unit of observation: dictator-recipient pair. Significance levels: * 10%, ** 5%, and *** 1%.

estimates are stable across 4 columns.

Looking at column 5, the coefficient estimate on $IQHigher_{ij} * Female_j$ is positive and statistically insignificant. To give a statistical claim about the insignificance, I use duality between hypothesis testing and confidence interval (Casella and Berger 2001) and examine what effect size we can reject and whether it is quantitatively important as typically done in epidemiology (e.g. Chaisemartin and Chaisemartin 2020). Thus turning to the 95% confidence

interval reported below the standard error estimate, the negative end is about -0.037, suggesting that we can reject the effect size lower than -3.7% of the dictator endowment at 5% significance level. This value is very small, about 2.4-3.1 times smaller than the effect size of typical dictator game experiments that examine the role of social distance with university students (e.g., Brañas-Garza et al. 2010; Charness and Gneezy 2008; Leider et al. 2010).¹⁵

Notes: This table shows OLS estimates of the role of the recipients' gender and IQ in dictators' allocation. The outcome variable is dictators' allocation as a fraction of endowment. The main specification is column 5 which includes all covariates (see the main text for detail). Columns 2-4 provide robustness of the main specification by excluding some covariates and column 1 shows bias of not including dictator IQ fixed effects. Baseline mean and standard deviation are mean and standard deviation of dictators' allocation in the omitted category (male recipients with lower IQ). The standard error (in parenthesis) and the 95% confidence interval (in bracket) are reported below each coefficient estimate. The standard errors are clustered at the dictator level with Pustejovsky and Tipton (2018)'s small cluster bias adjustment. Unit of observation: dictator's allocation. Significance levels: * 10%, ** 5%, and *** 1%.

While OLS only picks up the average effect, these observations hold also in distribution. Panel A of figure 4 presents empirical CDFs of dictators' allocation for each recipient category, residualized with the dictator's IQ fixed effects to give causal interpretation.¹⁶ The figure shows that the CDF of dictators' allocation to female recipients with higher IQ (solid blue line) almost

15. Charness and Gneezy (2008) examine how informing the recipient's family name increases the dictators' allocation using a university student sample, and find an 8.9% increase in allocation as a fraction of endowment. Leider et al. (2010) find using a university student sample that dictators increase allocation by 11.42% as a fraction of endowment for their friends relative to someone living in the same student dormitory. Brañas-Garza et al. (2010) also find using a university student sample that dictators give about 10% more of their endowment to friends relative to other students in the same class.

16. Residualized dictators' allocation is residual from regression of dictators' allocation on dictators' IQ fixed effects.

always lies to the right of the other CDFs (although all CDFs are statistically indistinguishable from each other at 5% significance level, obtained via Kruskal-Wallis permutation test (Young 2019) to address arbitrary dependency among observations), suggesting people do not treat competent women unfavorably than competent men.

The results also hold separately for male and female dictators. Column 1 of table 7 presents results with male dictators only and column 2 results with female dictators only, both will full control. First, the coefficient estimate on $IQHigher_{ij} * Female_j$ is positive and statistically insignificant both for male and female dictators. Second, while the 95% confidence interval is wider due to the reduction of sample size by about half, we can still reject at 5% significance level the effect size lower than -9.0% for male dictators and -3.5% for female dictators. -9.0% is still the magnitude of the effect size of typical dictator game experiments. As with the full sample estimate, these observations also hold in distribution as reported in panel B (male dictators) and in panel C (female dictators) of figure 4. For both male dictators and female dictators, the CDF of dictators' allocation to female recipients with higher IQ (solid blue line) almost always lies on the right of the other CDFs (although all CDFs are statistically indistinguishable from each other at 5% significance level), suggesting that neither men nor women do not treat competent women unfavorably than competent men.¹⁷

While dictators only see the recipients' IQ relative to theirs and thus the competence measure is relative to theirs, dictators do not see their IQ at the time they play dictator games. Indeed, in the real world, we do not have an absolute measure of other people's competence but evaluate relative to some benchmark. Yet, if anything, overconfident people is likely to consider people whose competence is higher than themselves as more competent in absolute terms than non-overconfident people do, after controlling for their actual competence.

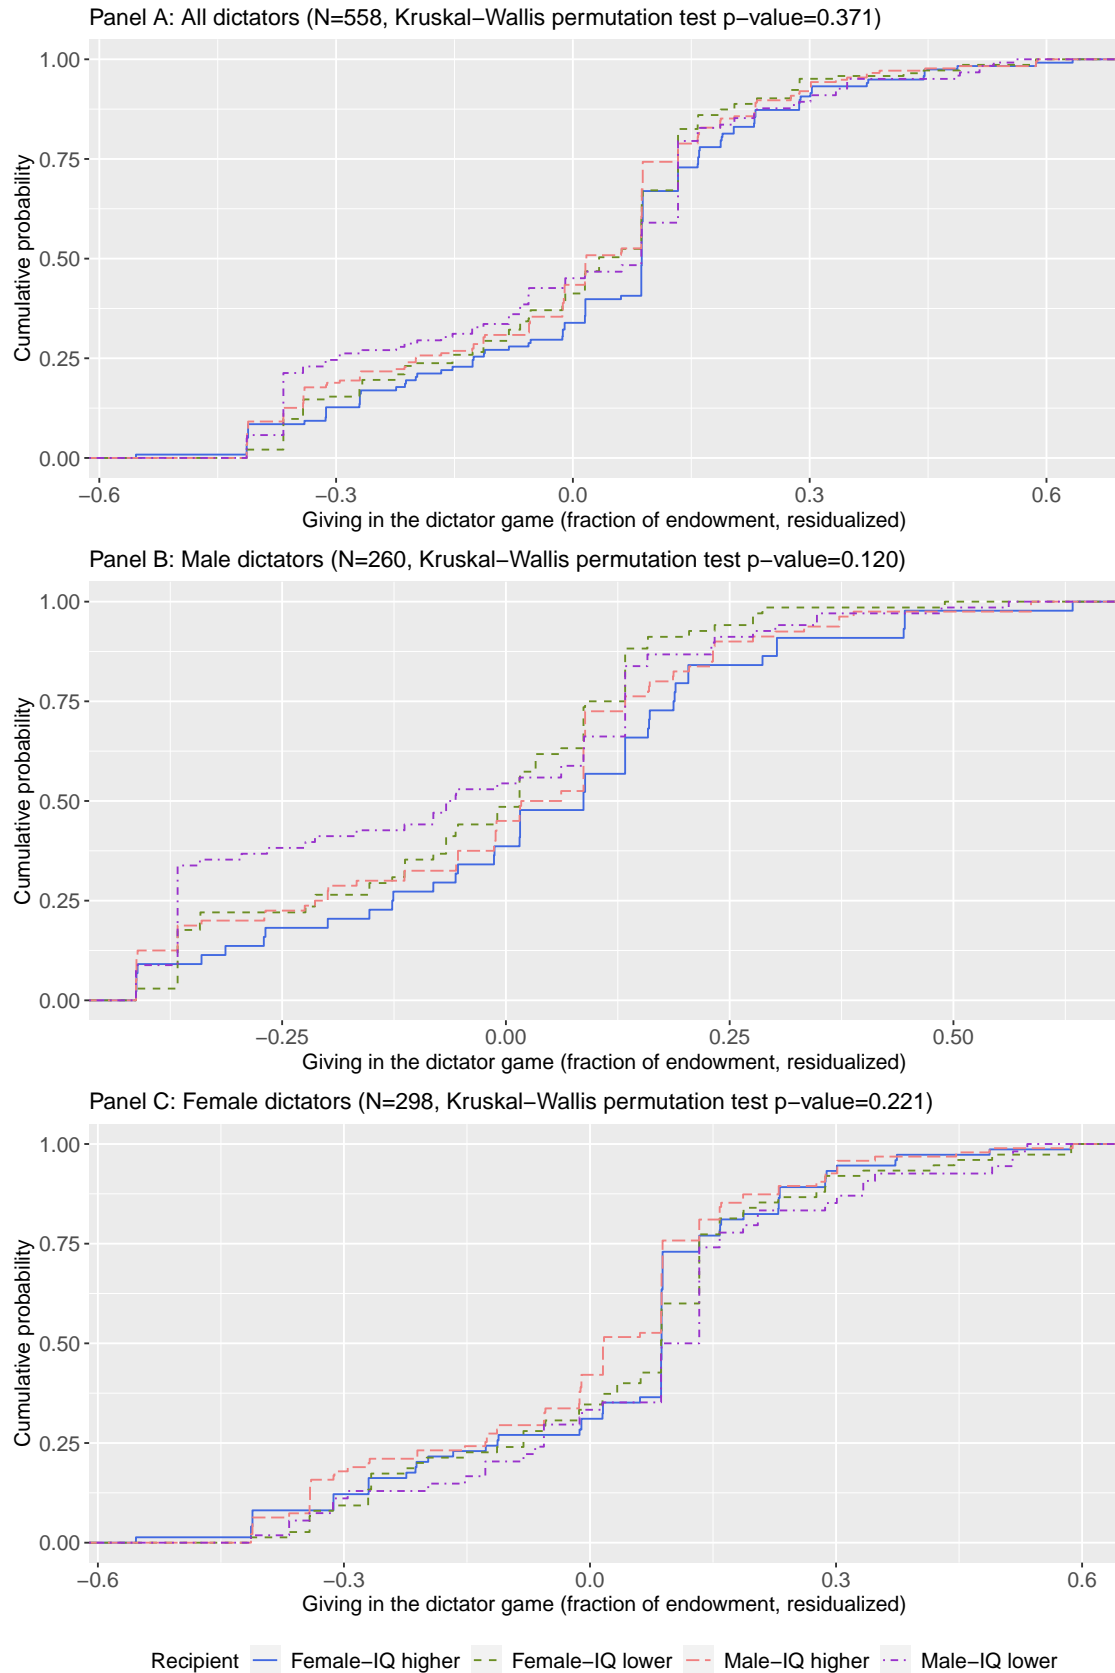

In columns 3-4 of table 7, I present the results separately for overconfident dictators (dictators who guess their IQ higher than their actual IQ, column 3) and non-overconfident dictators (dictators who guess their IQ equal to or lower than their actual IQ, column 4). For both types of dictators, the coefficient estimate on $IQHigher_{ij} * Female_j$ is positive and statistically insignificant and the lower bound of the estimate at 5% significance level is almost identical (-6.0% for over-confident dictators and -6.3% for non-overconfident dictators). Thus, relative or absolute does not matter for my main results.

4.3 Alternative explanations

Female dictators' in-group preference One competing explanation is female dictators' favoritism towards people who belong to the same social group, or in-group preference (Tajfel and Turner 1979), which biases my β_3 estimates upward. However, this explanation is inconsistent with the data. First, I use the difference in allocation between lower IQ female and male recipients as a control group, which eliminates the recipients' gender-specific allocation preference for analysis with female dictators. Second, the results with male dictators who do not have an in-group preference towards female recipients still reject the effect size lower than that of a

17. Table C1 presents the same summary statistics as table 2 but separately for female and male dictators and their differences. It shows that female dictators are more likely to major in humanities, less likely to major in social sciences and STEM, less overconfident, and tend to allocate more to recipients – characteristics consistent with the literature on gender differences (Croson and Gneezy 2009, e.g.).

FIGURE 4: CDFs OF DICTATORS' ALLOCATION BY THE RECIPIENTS' CATEGORY (RESIDUALIZED)

Notes: These figures show the empirical distribution of residualized dictators' allocation by recipients' category for all dictators (panel A), male dictators (panel B), and female dictators (panel C). Residualized dictators' allocation is residual from regression of dictators' allocation on dictators' IQ fixed effects. Kruskal–Wallis permutation test p-values are calculated using randomization inference (Young 2019) to address arbitrary dependency among observations with 2000 draws under the null hypothesis of no location difference (i.e. all CDFs coincide). Unit of observation: dictator's allocation.

TABLE 7: THE ROLE OF THE RECIPIENTS' GENDER AND IQ IN DICTATORS' ALLOCATION: ROBUSTNESS CHECKS

| Outcome: | Dictator's allocation (fraction of endowment) | | | | Belief on IQ |
|------------------------|-----------------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|

| Clusters | 91 | 104 | 115 | 80 | 193 |

Notes: This table shows OLS estimates of the role of the recipients' gender and IQ in dictators' allocation for male and female dictators (columns 1-2), overconfident and non-overconfident dictators (columns 3-4), and evaluators' belief on the recipients' IQ (column 5). The outcome variable is dictators' allocation as a fraction of endowment in columns 1-2 and evaluators' belief on the recipients' IQ level in column 5. All specifications include dictator IQ fixed effects, round fixed effects, proximity fixed effects, dictator (or evaluator) controls, and recipient controls, except columns 1 and 2 where dictator's gender dummy is excluded and columns 3-4 where dictator's overconfidence measure is excluded. Baseline mean and standard deviation are mean and standard deviation of dictators' allocation in the omitted category (male recipients with lower IQ). The standard error (in parenthesis) and the 95% confidence interval (in bracket) are reported below each coefficient estimate. The standard errors are clustered at the dictator or the evaluator level with Pustejovsky and Tipton (2018)'s small cluster bias adjustment. Unit of observation: dictator's allocation (columns 1-2) and evaluator's belief (column 3). Significance levels: * 10%, ** 5%, and *** 1%.

typical dictator game experiment studying the effect of social distance using a university student sample.

Distaste against lower IQ male recipients Although I use the difference in allocation to lower IQ female and male recipients to control for any recipient gender-specific allocation preference, this may not be a clean control because people may have a negative bias against under-performing men (Cappelen, Falch, and Tungodden 2019; Moss-Racusin, Phelan, and Rudman 2010). This explanation is also inconsistent with the data as shown by the allocation difference between higher IQ female and male recipients without using lower IQ female-male allocation differences, the estimate of $\beta_2 + \beta_3$. It still suggests we can reject at the 5% significance level that the effect size is lower than -1.1% of dictator endowment for all dictators (table 6, column 5), lower than -4.8% for male dictators (table 7, column 1), lower than -1.5% for female dictators (table 7).

A wrong belief that female recipients are less competent My empirical specification compares female and male recipients with higher IQ. The identification fails if dictators consider female recipients as less competent than male recipients even if they have a higher IQ than dictators. Although this is unlikely, Fiske et al. (2002) find that people consider women as less competent than men where the competence measures include intelligence.

This explanation indeed does not apply to my sample. Column 5 of table 7 presents results from a regression where I replace dictators' allocation with recipients' belief (whom I call evaluator) about the other recipients' IQ level which proxies dictators' belief. Recipients' belief is a valid proxy for dictators' belief by the random assignment of participants to dictators and recipients and that both dictators and recipients face the same environment until the start of the dictator game.¹⁸ The estimate of β_3 is positive albeit statistically insignificant, suggesting dictators do not believe that higher IQ female recipients are less competent than higher IQ male recipients.

This belief analysis, however, points to a potentially interesting difference in people's belief updating process about women's and men's competence: people may update women's competence more than men's competence once they see an objective measure of women's competence as shown by the positive but statistically insignificant estimate of β_3 .

Lack of statistical power When the power is low (type II error rate is high), the confidence interval becomes wider. However, my confidence interval can reject a small effect size at a 5% significance level. Also, while there is an ex-post minimum detectable effect estimate, it is simply 2.8 times the standard error and mostly useful for cross-study comparison (McKenzie and Ozier 2019); the information contained in the confidence interval is strictly larger than the information contained in the ex-post minimum detectable effect.

4.4 Further subsample analysis

To further address the robustness of the main results, table C3 presents results for various subsamples and we can still reject the effect size lower than -4.3% to -8.7% at 5% significance level.¹⁹ Last, while I pool all the higher and lower IQ recipients despite that dictators can also see the IQ rank differences, figure C2 shows that taking into account the IQ rank differences does not alter the results.²⁰

There seems to be an order effect, however, as shown in table C3, columns 4-6. It is difficult to interpret them, but the bottom line is that the statistically significant estimates $-\beta_3$ and $\beta_2 + \beta_3$ are both positive and provide evidence against that competent women receive lower allocation.

18. Table C2 presents evidence that recipients and dictators do not differ in their observable characteristics and characteristics of paired recipients.

19. In table C3, column 1 excludes dictators with IQ rank 1 and 6 who never face recipients with lower / higher IQ. Column 2 excludes dictator-recipient pairs in which the dictator knows the recipients even a little and column 3 pairs in which the dictator saw the recipients before.

20. Figure C2 shows OLS estimates of equation 1 but splitting $IQHigher_{ij}$ into 6 separate dummies indicating the recipients' IQ rank differences relative to the dictators'. The lower/higher the recipient's IQ, the more negative/positive their IQ rank difference. For brevity, the figure only plots the coefficient estimates on the interaction terms between the 6 separate $IQHigher_{ij}$ and $Female_j$, $\hat{\beta}_3$ along with their 95% confidence intervals.

5 Conclusion

This paper examines whether competent women receive unfavorable treatment compared to competent men. Using dictator game allocation as a measure of favorable and unfavorable treatment and exogenously varying gender and competence measured by an IQ test, I show that people treat competent women no less favorably than competent men; if anything, people treat competent women slightly more favorably. The lower bound of my estimate is -3.7% of dictator endowment, which is much smaller than the effect size of dictator game experiments studying the role of social distance.

This paper contributes to the literature in two ways. First, I provide evidence that, in the stylized environment where unfavorable treatment has material consequences, the argument that women face a tradeoff between being competent and being likable does not hold. This suggests that competent women may receive fair treatment in hiring and promotion if the results are externally valid. Second, while several studies show that women are more critically evaluated in traditionally male occupations, my results indicate that a plausible explanation for this evidence is people’s lack of enough prior about women’s competence in these occupations rather than taste-based gender discrimination.

Indeed, there is ample evidence that female leaders (Chakraborty and Serra 2020; Håkansson 2020) and competitors (Datta Gupta, Poulsen, and Villeval 2013) receive more aggressive treatments and receive less support by men (Born, Ranehill, and Sandberg 2020). My study is silent to gender discrimination where there are intense interactions and competition among women and men; there is evidence that men hold motivated gender bias – view women in a gender stereotypical way only when those women criticize them (Sinclair and Kunda 2000) – and it is a topic of future research. Still, my results apply to vertical relationships such as workers vs. managers and employees vs. employers where competition is less intense than horizontal relationships such as workers vs. workers, and provide a piece of evidence in considering hiring and promotion practices in labor markets.

Another limitation of this study is that being perceived as less likable can negatively impact competent women’s workplace performance even if it has no material consequence. It can also discourage them to enter competition in the first place. Yet, my study still shows that once they convince people around them about their competence, they receive a fair treatment in hiring and promotion.

Appendix A Changes to the pre-analysis plan

In the initial design, recipients finished all the tasks except the post-questionnaire and left the laboratory before dictators receive their IQ rank, so that dictators could play dictator game without recipients in the same room. The allocation to the recipients was paid electronically as a “participation fee” for the online post-questionnaire which was sent to recipients via email after the session was over. However, as I ran the 1st session with this initial design with 24 participants, dictators had to wait idly for about 20-30 minutes until recipients left the laboratory and dictators seemed to have lost concentration during this period: about half of the dictators could not answer the comprehension questions about their IQ rank. Thus, I changed the design and let recipients stay in the laboratory while dictators played the dictator game. I looked at the 1st session data before making this change. I exclude the 1st session data in the analysis, but results including the 1st session data delivers the same conclusion and available upon request. Also, the oTree code and instructions used for the 1st session are available upon request.

I also made the following minor changes after the 1st session:

1. I reduced participation fee from 3€ to 2.5€ because participants earned more than I expected in the IQ test.
2. I added more explanation to the instructions on how the IQ rank was assigned and how to allocate endowment in the dictator game.
3. I asked participants’ major by simply choosing among the choices from humanities, social sciences, natural sciences/mathematics, medicine, and engineering and letting them type in their degree program name for a check, instead of letting them access to the University of Bologna’s degree program website. This is because the computers in the laboratory sometimes did not accept `iframe` or prevented a pop-up to another website due to the security setting.

Other changes are the following:

Interpretation and focus:

1. I rephrased smartness as competence to better place my results in the literature.
2. I mainly discussed results for question 3.

Analysis:

3. I corrected the definition of $Lower_{ij}$. Consequently, I renamed it as $IQHigher_{ij}$ to make the meaning clearer.
4. I added distributional analysis (in figure 4) to examine whether the results hold also in distribution.
5. I added round-by-round analysis in table C3.
6. I used `lm_robust` instead of `vcovCR` to apply Pustejovsky and Tipton (2018)’s small cluster bias adjustment because `vcovCR` did not make degrees of freedom adjustment.
7. I included in female and male dictator regressions STEM major dummy and Emilia-Romagna dummy because excluding them in regressions where the sample is conditioned by gender made little sense. The results are invariant to the exclusion of these covariates.
8. I divided dictators’ allocation by dictator endowment to facilitate the interpretation of the regression results (this does not affect my results because of the round fixed effects).

Appendix B Description of covariates

X_{ij} in the main specification (equation 1) includes the following variables:

Dictator characteristics

- $Age_i \in \mathbb{N}$: dictator i 's age.
- $Female_i \in \{0, 1\}$: an indicator variable equals 1 if dictator i is female, 0 otherwise.
- $FromEmiliaRomagna_i \in \{0, 1\}$: an indicator variable equals 1 if dictator i is from Emilia-Romagna region (where the University of Bologna is located), 0 otherwise.
- $SocialSciences_i \in \{0, 1\}$: an indicator variable equals 1 if dictator i 's major is social sciences, 0 otherwise.
- $STEM_i \in \{0, 1\}$: an indicator variable equals 1 if dictator i 's major is natural sciences/mathematics, engineering, or medicine; 0 otherwise.
- $PostBachelor_i \in \{0, 1\}$: an indicator variable equals 1 if dictator i 's degree program is either master/post-bachelor, in the 4th year or beyond of bachelor-master combined program, or PhD, 0 otherwise.²¹
- $OverConfidence_i \in \{-1, 0, 1\}$: degree of dictator i 's overconfidence. It is equal to -1 if dictator i 's guess about the number of IQ test questions they correctly solved is lower than the actual number, 0 if equal to the actual number, and 1 if higher than the actual number.

Recipient characteristics

- $Age_j \in \mathbb{N}$: recipient j 's age.
- $FromEmiliaRomagna_j \in \{0, 1\}$: an indicator variable equals 1 if recipient j is from Emilia-Romagna region, 0 otherwise.

Fixed effects

- $\sum_{l=2}^3 r^l$: round fixed effects where $r^l \in \{0, 1\}$ is an indicator variable equals 1 if the round is equal to $l=1, 2, 3$, 0 otherwise.
- $\sum_{l=2}^3 q_{ij}^l$: proximity fixed effects where $q_{ij}^l \in \{0, 1\}$ is an indicator variable showing the proximity between dictator i and recipient j , and equals 1 if dictator i does not know recipient j at all ($l=1$), has seen before ($l=2$), knows but not very well ($l=3$).

21. In Italy, bachelor is a 3 year program.

Appendix C Additional figures and tables

FIGURE C1: DENSITY AND DISTRIBUTION OF THE DICTATORS' ALLOCATION

Notes: These figures show the empirical density (panel A) and the empirical distribution (panel B) of the dictators' allocation as a fraction of endowment. Recipients whose name is non-Italian sounding and whom the dictator declared they knew them "very well" at least once are excluded. Unit of observation: dictator's allocation.

FIGURE C2: THE ROLE OF THE RECIPIENTS' IQ AND GENDER IN DICTATORS' ALLOCATION: TAKING INTO ACCOUNT FOR IQ RANK DIFFERENCES

Notes: This figure shows OLS estimates of the role of recipient's gender and IQ in dictators' allocation that takes into account for the IQ rank differences dictators observe by splitting $IQHigher_{ij}$ into 6 separate dummies indicating the recipients' IQ rank differences relative to the dictators'. The lower/higher the recipient's IQ, the more negative/positive their IQ rank difference. The specification includes dictator IQ fixed effects, round fixed effects, proximity fixed effects, dictator controls, and recipient controls. The outcome variable is dictators' allocation as a fraction of endowment. For brevity, the figure only plots the coefficient estimates on the interaction terms between the 6 separate $IQHigher_{ij}$ and $Female_j$, $\hat{\beta}_3$, along with their 95% confidence intervals, which is calculated with standard errors clustered at dictator level with Pustejovsky and Tipton (2018)'s small cluster bias adjustment. Unit of observation: dictator's allocation.

TABLE C1: SUMMARY STATISTICS: DICTATOR DATA BY GENDER

| | Female | | Male | | Difference |
|---------------------------------------------------------------|--------|-------|--------|--------|------------|
| | Mean | SD | Mean | SD | p-value |
| <i>Panel A: Dictators</i> | | | | | |
| IQ level | 6.52 | 1.20 | 6.89 | 1.24 | 0.04 |

| From Emilia-Romagna | 0.15 | 0.36 | 0.25 | 0.43 | 0.01 |
| Observations | 298 | | 260 | | |
| <i>Panel C: Proximity</i> | | | | | |
| Did not know at all | 0.98 | 0.15 | 0.95 | 0.23 | 0.07 |
| Knew but not well | 0.02 | 0.15 | 0.03 | 0.18 | 0.44 |
| Saw before | 0.00 | 0.00 | 0.02 | 0.14 | 0.02 |
| Observations | 298 | | 260 | | |
| <i>Panel D: Dictator's allocation (fraction of endowment)</i> | | | | | |
| Allocation | 0.43 | 0.22 | 0.37 | 0.25 | 0.00 |
| Allocation (residualized) | | 0.22 | | 0.25 | |
| Observations | 298 | | 260 | | |

Notes: This table shows summary statistics separately for female and male dictators: the dictators' and the paired recipients' characteristics, how well dictators knew the paired recipients, and dictators' allocation. Recipients whose name is non-Italian sounding and whom the dictator declared they knew them "very well" at least one are not included. Standard deviation of residualized allocation is standard deviation of residual of regression of the dictator game allocation as a fraction of endowment on IQ fixed effects. P-values for difference in means are calculated with the two-sample t-test with HC2 heteroskedasticity-robust standard errors with Bell and McCaffrey (2002)'s small sample bias adjustment.

TABLE C2: SUMMARY STATISTICS: EVALUATOR DATA VS. DICTATOR DATA

| | Evaluator | | Dictator | | Difference |
|----------------------------------------------|-----------|-------|----------|-------|------------|
| | Mean | SD | Mean | SD | p-value |
| <i>Panel A: Evaluator / Dictator</i> | | | | | |
| IQ level | 6.84 | 1.14 | 6.69 | 1.23 | 0.21 |
| IQ rank | 3.40 | 1.74 | 3.58 | 1.67 | 0.30 |
| Age | 23.34 | 2.78 | 23.47 | 2.72 | 0.63 |
| From Emilia-Romagna | 0.20 | 0.40 | 0.18 | 0.39 | 0.76 |

| Social sciences | 0.27 | 0.44 | 0.19 | 0.40 | 0.08 |
| STEM | 0.39 | 0.49 | 0.35 | 0.48 | 0.42 |
| Post bachelor | 0.49 | 0.50 | 0.46 | 0.50 | 0.48 |
| Overconfidence | 0.49 | 0.75 | 0.43 | 0.76 | 0.42 |
| Time on feedback (sec.) | 93.26 | 83.96 | 107.60 | 95.60 | 0.12 |
| Observations | 193 | | 195 | | |
| <i>Panel B: Paired recipients</i> | | | | | |
| IQ level | 6.84 | 1.16 | 6.84 | 1.16 | 1.00 |
| IQ rank | 3.42 | 1.74 | 3.42 | 1.74 | 0.98 |
| IQ higher | 0.50 | 0.50 | 0.53 | 0.50 | 0.46 |
| Age | 23.35 | 2.80 | 23.35 | 2.77 | 0.99 |
| Female | 0.47 | 0.50 | 0.47 | 0.50 | 0.99 |
| From Emilia-Romagna | 0.19 | 0.40 | 0.20 | 0.40 | 0.87 |
| Observations | 368 | | 558 | | |
| <i>Panel C: Proximity</i> | | | | | |
| Did not know at all | 0.98 | 0.14 | 0.96 | 0.19 | 0.08 |
| Knew but not well | 0.02 | 0.14 | 0.03 | 0.17 | 0.34 |
| Saw before | 0.00 | 0.00 | 0.01 | 0.09 | 0.03 |
| Observations | 368 | | 558 | | |
| <i>Panel D: Belief on the recipient's IQ</i> | | | | | |
| Belief on IQ level | 6.34 | 1.89 | | | |
| Belief on IQ level (residualized) | | 1.87 | | | |
| Observations | 368 | | | | |

Notes: This table shows summary statistics for the evaluators and dictators: the evaluators'/dictators' and the paired recipients' characteristics, how well evaluators/dictators knew the paired recipients, and evaluators' belief. Recipients whose name is non-Italian sounding and whom the dictator declared they knew them "very well" at least one are not included. Standard deviation of residualized belief is standard deviation of residual of regression of the evaluators' belief on the paired recipients' IQ level on IQ fixed effects. P-values for difference in means are calculated with the two-sample t-test with HC2 heteroskedasticity-robust standard errors with Bell and McCaffrey (2002)'s small sample bias adjustment.

TABLE C3: THE ROLE OF THE RECIPIENTS' GENDER AND IQ IN THE DICTATORS' ALLOCATION: FURTHER ROBUSTNESS CHECKS

| Outcome: | Dictator's allocation (fraction of endowment) | | | | | |
|------------------------|-----------------------------------------------|-------------------------------------|-------------------------------------|--------------------------------------|--------------------------------------|--------------------------------------|
| Sample: | Excluding IQ rank 1 and 6 | Excluding proximity 3 | Excluding proximity 2 and 3 | Round 1 | Round 2 | Round 3 |
| | (1) | (2) | (3) | (4) | (5) | (6) |
| IQHigher | 0.006 (0.036) [-0.065, 0.077] | 0.011 (0.033) [-0.056, 0.077] | 0.005 (0.034) [-0.062, 0.073] | 0.021 (0.055) [-0.088, 0.131] | 0.053 (0.056) [-0.058, 0.165] | -0.038 (0.069) [-0.175, 0.099] |
| Female | 0.019 (0.029) [-0.040, 0.077] | 0.006 (0.026) [-0.045, 0.058] | 0.008 (0.027) [-0.046, 0.062] | 0.040 (0.050) [-0.059, 0.139] | 0.053 (0.049) [-0.044, 0.150] | -0.063 (0.057) [-0.175, 0.049] |
| IQHigherxFemale | 0.001 (0.044) [-0.087, 0.088] | 0.029 (0.037) [-0.043, 0.102] | 0.029 (0.038) [-0.047, 0.104] | -0.057 (0.072) [-0.199, 0.085] | -0.057 (0.069) [-0.194, 0.080] | 0.190** (0.074) [0.044, 0.337] |
| Female+IQHigherxFemale | 0.019 (0.034) [-0.047, 0.086] | 0.036 (0.026) [-0.016, 0.087] | 0.037 (0.026) [-0.015, 0.088] | -0.017 (0.05) [-0.116, 0.083] | -0.004 (0.05) [-0.102, 0.093] | 0.127** (0.05) [0.029, 0.225] |
| Baseline Mean | 0.391 | 0.373 | 0.377 | 0.384 | 0.351 | 0.382 |
| Baseline SD | 0.240 | 0.262 | 0.261 | 0.245 | 0.268 | 0.279 |
| R-squared | 0.102 | 0.083 | 0.079 | 0.082 | 0.159 | 0.167 |
| Observations | 386 | 553 | 537 | 185 | 187 | 186 |
| Clusters | 135 | 195 | 194 | - | - | - |

Notes: This table shows OLS estimates of the role of recipient's gender and IQ in dictators' allocation for various subsamples. The outcome variable is allocation in the dictator game as a fraction of endowment. All specifications include dictator IQ fixed effects, dictator controls, and recipient controls. All columns except column 3 additionally include proximity fixed effects and columns 1-3 round fixed effects. Baseline mean and standard deviation are mean and standard deviation of dictators' allocation in the omitted category (male recipients with lower IQ). The standard error (in parenthesis) and the 95% confidence interval (in bracket) are reported below each coefficient estimate. Standard errors are clustered at dictator level with Pustejovsky and Tipton (2018)'s small cluster bias adjustment for columns 1-3 and HC2 heteroskedasticity-robust with Bell and McCaffrey (2002)'s small sample bias adjustment for columns 4-6. Unit of observation: dictator's allocation. Gelman and Carlin (2014)'s type M error ratio for coefficient estimate on IQHigherxFemale in column 6 is 2.509 and type S error rate is 0.010, where I use the true value from the pre-analysis plan: $-0.47/(7+5+7)*3 \approx -0.074$ (I divided -0.47 by the average of dictator endowment). Significance levels: * 10%, ** 5%, and *** 1%.

Appendix D Experimental instructions

Pre-experiment: Random desk assignment & photo taking

Upon arriving the laboratory, we check participants' ID one by one and ask them to draw a coin with a number on it from an opaque back. We ask participants to take a desk corresponding to the number of the coin they have just drawn and hand them the information and privacy form, which they have to sign in order to participate in the experiment. Then participants take their facial photo at a photo booth.

When the number of participants show up to the laboratory is not a multiple of 6, I randomly choose excess participants (e.g. 3 participants if the total number of participants is 21) and ask them to leave the laboratory without participating. Those who leave the laboratory receive 5€.

Once all participants finish these procedures and the excess participants leave the laboratory, we start the oTree program. Participants see the following screen in which they enter their desk number.

FIGURE D1: INTRODUCTION PAGE 1

Please enter your desk number and click "Next"

Your desk number:

Next

After that, they see the following screen in which they see their facial photo taken at the photo booth (they see their facial photo instead of the green circle in the actual screen). Then, they enter their first name. We go to each desk and check that the photo and the first name match the participant sitting in the desk to ensure all participants that other participants' photo and first name are real, following Isaksson (2018). After this check, we enter the digital signature and let the participants proceed to the next page.

FIGURE D2: INTRODUCTION PAGE 2

Please check that the photo is yours

The photo you took is displayed above. Please check that the photo is yours. Please also enter your first name. We will come to each desk and check the photo and the first name.

Your first name:

Digital signature (please wait for us to sign you in):

Next

Participants then see the following screen, which we read aloud. The grey box appear in the bottom of every page after this page for their reference.

FIGURE D3: INTRODUCTION PAGE 3

Welcome!

You are participating in a study of the BLESS. For your participation, you will receive a fixed amount of 2,5€. There are 2 parts in which you can earn additional earnings. The expected length is 1 hour.

During the study, we use your photo and first name to identify you. Your photo and the first name will only be used in this session and deleted immediately afterwards. However, we may ask some of you to allow us to use their photo in another study, which you can opt out.

The study is computerized, meaning that the computer program will give you precise instructions in each task. In the following you will find general instructions of the study, which you can always find in the bottom of the screen.

General instructions

- Please turn off your mobile phone.
- Please do not communicate with other participants.
- Please only use paper and pencil.
- Once you understand the instructions or enter your decisions, please click "Next" to proceed unless instructed otherwise.
- If you have any questions, please raise your hand at any time.

If there is no question, we will start the study.

Part 1: IQ test

After the general instructions, participants start the IQ test. They first see the following instructions where “Raven’s SPM no. 31” is replaced with the Raven’s Standard Progressive Matrix 31 in the actual screen. After clicking “Next,” they will see a set of 9 IQ test questions: the Raven’s Standard Progressive Matrices 11, 24, 28, 36, 43, 48, 49, 53, and 55. They have 9 minutes to complete these 9 questions and they see a countdown on the top of the screen.

FIGURE D4: IQ TEST INSTRUCTIONS PAGE

Part 1: Instructions

In part 1, you will work on an IQ test, which is frequently used to measure intelligence. The IQ test you will work on is the Raven’s Standardized Progressive Matrices Test.

You will solve the IQ test as follows: for each question, you will see an image in which a piece is missing. Below the image there will be several options. Choose the correct option among them to complete the image. There will be only one correct option.

An example is provided below. In the image, there are 9 large white squares each containing a small black square. In the first column, the small black square is located on the left; in the second column, in the middle; in the third column, on the right. In the first row, it is located on the top; in the second row, in the middle; in the third row, in the bottom. Thus, in the third column of the third row, the small black square must be located in the right bottom, thus the correct option is 5.

Raven’s SPM no. 31

There are 9 questions in total and you have 9 minutes. Once the time is over, you will automatically be directed to the next page. You will earn 0,5€ for each correct answer. There is no penalty for wrong answers. You can use paper and pencil on your desk.

Next

After they finish the IQ test, participants see the following screen in which they are asked to guess the number of IQ test questions they have solved correctly.

FIGURE D5: GUESSING PAGE

Guess the number of questions you solved

The IQ test is over.

We have randomly formed a group of 6 participants including you in this room and constructed a ranking among the 6 group members based on their IQ test performance.

A group member with rank 1 performed the best in the IQ test, followed by a group member with rank 2, 3, 4, 5, and 6. In case of a tie between group members, the computer randomly decided who receives the higher rank.

How many questions do you think you have solved correctly? If your guess is correct, you will additionally earn 0,5€.

Next

Then participants receive their IQ ranking within a group of 6 participants. The group was formed based on their oTree participant ID which was pre-assigned to each desk. They are asked to answer how many people in their group performed better and worse than them in order to proceed.

FIGURE D6: COMPREHENSION QUESTIONS PAGE

Feedback

Among your 6 group members including you, you received **Rank 4**.

Among your 6 group members, how many people performed better than you in the IQ test?

Among your 6 group members, how many people performed worse than you in the IQ test?

Part 2: Dictator game

Then half of the participants in a given group become dictators and see the following instructions pages. Dictator is called “active participant” and told that their decision will not be known to anyone except us.

FIGURE D7: DICTATOR INSTRUCTIONS PAGE 1 (DICTATORS ONLY)

Part 2: Instructions

In this part, half of you will be active participants who will work on the task described in the next page, and the remaining half will be passive participants who will NOT work on the task described in the next page.

Next

FIGURE D8: DICTATOR INSTRUCTIONS PAGE 2 (DICTATORS ONLY)

Part 2: Instructions

You are assigned to a role of **active participant**.

Part 2 consist of 3 rounds. In each round, you will first receive an endowment (money). After that, you will be paired with a passive participant in your group.

Your task in this part is to allocate the endowment to yourself and the paired passive participant. The passive participants, other active participants, or anyone else other than us will never know who allocated how much.

At the end of the study, the computer will randomly select 1 out of 3 rounds and the amount you allocated to you in that round will be your earnings in this part.

The computer will also randomly select 1 out of 3 rounds for the paired passive participants and the amount you allocated to him or her in that round will be his or her earnings in this part.

Next

After the instructions, dictators see the following set of screens 3 times, each time with a different recipient, in which they move the cursor of the slider to determine the allocation:

FIGURE D9: DICTATOR GAME PAGE 1 (DICTATORS ONLY)

Round 1 of 3

Time left to complete this page: **0:02**

Please wait.

FIGURE D10: DICTATOR GAME PAGE 2 (DICTATORS ONLY)

Round 1 of 3

Giovanna

Rank 5

You have received **7€** for this round.

You have been paired with **Giovanna**.

Please allocate the endowment between yourself and Giovanna. When you click the line below, a cursor appears. You can move the cursor by dragging it. Please move the cursor to your preferred position to determine the allocation.

You Giovanna

Next

The cursor is initially hidden to avoid anchoring until the dictators click the slider bar:

FIGURE D11: DICTATOR GAME PAGE 2 AFTER CLICKING THE SLIDER BAR (DICTATORS ONLY)

Please allocate the endowment between yourself and Giovanna. When you click the line below, a cursor appears. You can move the cursor by dragging it. Please move the cursor to your preferred position to determine the allocation.

You Giovanna

Next

After playing dictator game 3 times, dictators are asked to answer how well they know each of the paired recipients. The choices are: (i) “I didn’t know him/her at all,” “I saw him/her before,” “I knew him/her but not very well,” and “I knew him/her very well.”

FIGURE D12: DICTATORS' PROXIMITY CHECK PAGE (DICTATORS ONLY)

Round 3 of 3

Below we display the participants whom you were paired with. How well did you know him/her before participating in this study?

|  |  |  |
| Giovanna | Caterina | Paolo |
| <input type="text" value="I saw him/her before"/> | <input type="text" value="I didn't know him/her at all"/> | <input type="text" value="I didn't know him/her at all"/> |
| <input type="button" value="Next"/> | | |

Recipients, on the other hand, are not told that dictators are playing dictator game. Instead, they are asked to make guesses on the number of IQ test questions the other 2 recipients have solved correctly:

FIGURE D13: RECIPIENT INSTRUCTIONS PAGE (RECIPIENTS ONLY)

Part 2: Instructions

In part 2 consists of 2 rounds. In each round, you will be paired with another participant in your group.

Your task in this part is to guess how many questions the paired participant has solved correctly in the IQ test. For each correct guess, you will earn 0,5€.

After the instructions, recipients see the following screen 2 times, each time with different recipient, in which they enter their guess.

FIGURE D14: GUESSING PAGE (RECIPIENTS ONLY)

Round 1 of 2

Paolo

Rank 1

You have been paired with **Paolo**.

How many questions do you think Paolo has solved correctly?

Next

After they finish 2 guesses, recipients are also asked how well they know each of the paired recipients, just like dictators are asked.

FIGURE D15: RECIPIENTS' PROXIMITY CHECK PAGE (RECIPIENTS ONLY)

Round 2 of 2

Below we display the participants whom you were paired with. How well did you know him/her before participating in this study?

Caterina

I didn't know him/her at all

Paolo

I knew him/her but not very well

Post-experiment: Questionnaire

After the 3 rounds of the dictator game and the 2 rounds of the guessing are over, participants are told their earnings from the IQ test, dictator game, and the guesses. Before receiving their earnings, participants answer a short questionnaire.

Since dictators and recipients do different activities during the dictator game, they receive slightly different information. The following screen is for dictators:

FIGURE D16: DICTATORS' RESULTS AND EARNINGS INFORMATION PAGE (DICTATORS ONLY)

Results

The study is over. The results are provided below.

- In part 1, you solved **0** questions and earned **0,0€**. You have additionally earned **0,5€** because your guess about the number of questions solved was correct.
- In part 2, computer selected **round 2** in which you allocated **5,0€** to yourself.

So, your total earnings are **8,0€** including 2,5€ of participation fee.

Thank you for participating in this study! We will prepare your payment soon. Meanwhile, please answer a short questionnaire by clicking "Next." Your answer will be kept anonymous and will not affect your payment.

Next

The following screen is for recipients:

FIGURE D17: RECIPIENTS' RESULTS AND EARNINGS INFORMATION PAGE (RECIPIENTS ONLY)

Results

The study is over. The results are provided below.

- In part 1, you solved **0** questions and earned **0,0€**. You have additionally earned **0,5€** because your guess about the number of questions solved was correct.
- In part 2, you made **2** guesses correct. So you earned **1,0€**.
- You additionally earned a top-up of **0,0€**.

So, your total earnings are **4,0€** including 2,5€ of participation fee.

Thank you for participating in this study! We will prepare your payment soon. Meanwhile, please answer a short questionnaire by clicking "Next." Your answer will be kept anonymous and will not affect your payment.

Next

After the results and earnings information page, participants answer a 3-page questionnaire. The questionnaire slightly differs for dictators and recipients. The following set of screens is for dictators:
